

Problem 1. Absolute Permutation

OS Linux

We define P to be a permutation of the first n natural numbers in the range $[1, n]$. Let $pos[i]$ denote the value at position i in permutation P using 1-based indexing.

P is considered to be an *absolute permutation* if $|pos[i] - i| = k$ holds true for every $i \in [1, n]$.

Given n and k , print the lexicographically smallest absolute permutation P . If no absolute permutation exists, print `-1`.

Example

$n = 4$

$k = 2$

Create an array of elements from 1 to n , $pos = [1, 2, 3, 4]$. Using 1 based indexing, create a permutation where every $|pos[i] - i| = k$. It can be rearranged to $[3, 4, 1, 2]$ so that all of the absolute differences equal $k = 2$:

$pos[i]$	i	$ pos[i] - i $
3	1	2
4	2	2
1	3	2
2	4	2

Function Description

Complete the *absolutePermutation* function in the editor below.

absolutePermutation has the following parameter(s):

- *int* n : the upper bound of natural numbers to consider, inclusive
- *int* k : the absolute difference between each element's value and its index

Returns

- *int* $[n]$: the lexicographically smallest permutation, or $[-1]$ if there is none

Input Format

The first line contains an integer t , the number of queries.

Each of the next t lines contains 2 space-separated integers, n and k .

Constraints

- $1 \leq t \leq 10$
- $1 \leq n \leq 10^5$
- $0 \leq k < n$

Input		Output
STDIN	Function	2 1 1 2 3 -1
-----	-----	
3	t = 3 (number of queries)	
2 1	n = 2, k = 1	
3 0	n = 3, k = 0	
3 2	n = 3, k = 2	

Explanation

Test Case 0:

Position	1	2
Permutation	2	1
Absolute Difference	1	1

Test Case 1:

Position	1	2	3
Permutation	1	2	3
Absolute Difference	0	0	0

Test Case 2:

No absolute permutation exists, so we print **-1** on a new line.
